## Optimal Bass Reflex Loudspeaker Port Design

Andri Bezzola | Samsung Research America | Audio Lab

2019/10/03

# Loudspeaker Ports

- Mass of air in port and compliance of air in enclosure form a resonator
- Bass reflex (vented) can be abstracted to a 2-Mass-Spring-Damper System
- Excursion of the diaphragm is reduced compared to a sealed box with same SPL
- Nonlinear distortions are reduced

# Turbulence, Vortex Shedding, and Port Noise

- At high output, air in port tube can become turbulent
- Flow separation and vortex shedding occurs
- Experience tells us that continuously flared port tubes sound better
- *How much flare is optimal?*
- Fully turbulent models are numerically expensive and impractical as design tools

# Flow Separation and Vortex Shedding

Stream-wise momentum equation:

$$u \frac{\partial u}{\partial s} = -\frac{1}{\rho} \frac{dp}{ds} + \nu \frac{\partial^2 u}{\partial y^2}$$

- Adverse pressure gradient when  $\frac{dp}{ds} > 0$
- $u$  can become zero or negative

Effect of flow separation:

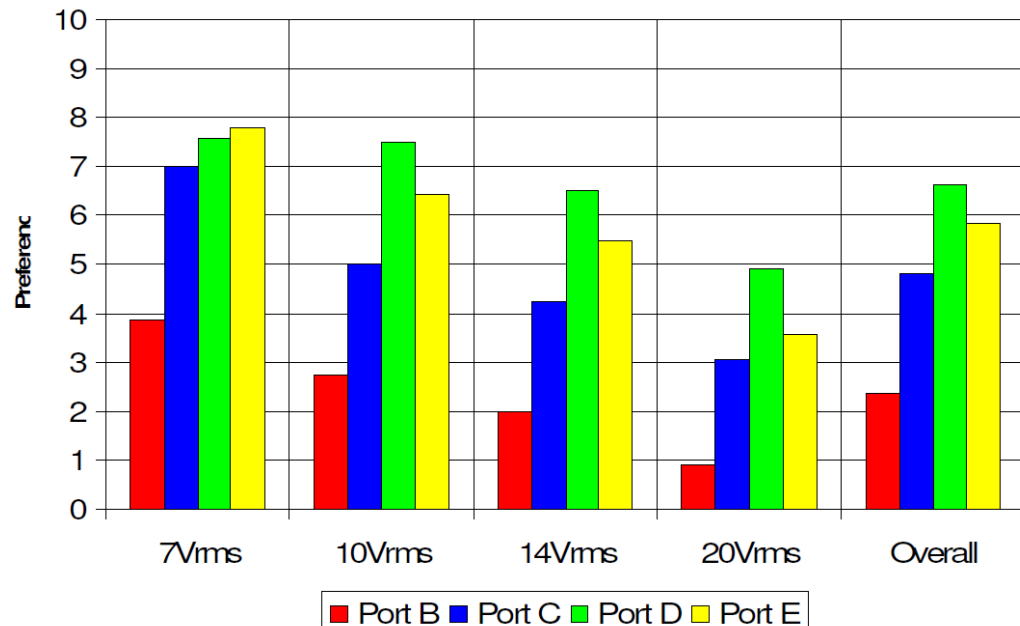

- Flow separation leads to vortex shedding
- Impulse-like excitation of air in port tube
- Excitation of *port eigenfrequencies*

$$f_p^1 = \frac{c}{\lambda} \approx \frac{c}{2L}$$

# Old Research Revisited

- Which port profile has the lowest propensity to generate turbulence, flow separation, and vortex shedding?
- Simulated 4 port geometries from Rapoport and Devantier <sup>[1]</sup>

Velocity Contours

<sup>[1]</sup> Rapoport, Z. and Devantier, A., "Analysis and Modeling of the Bi-Directional Fluid Flow in Loudspeaker Ports," in Audio Engineering Society Convention 117, San Francisco, (2004)

# Hypothesis

*“The best sounding port has the lowest propensity for flow separation.*

*Flow separation is minimal when the particle velocity contours at port exit have minimal curvature.”*

# Plan for Verification of Hypothesis

## Simulation

- Design 'optimal' ports of different  $L/D_0$  aspect ratios
- Construct slightly under- and over-flared ports
- Maintain tuning frequency for all ports

## Measurement

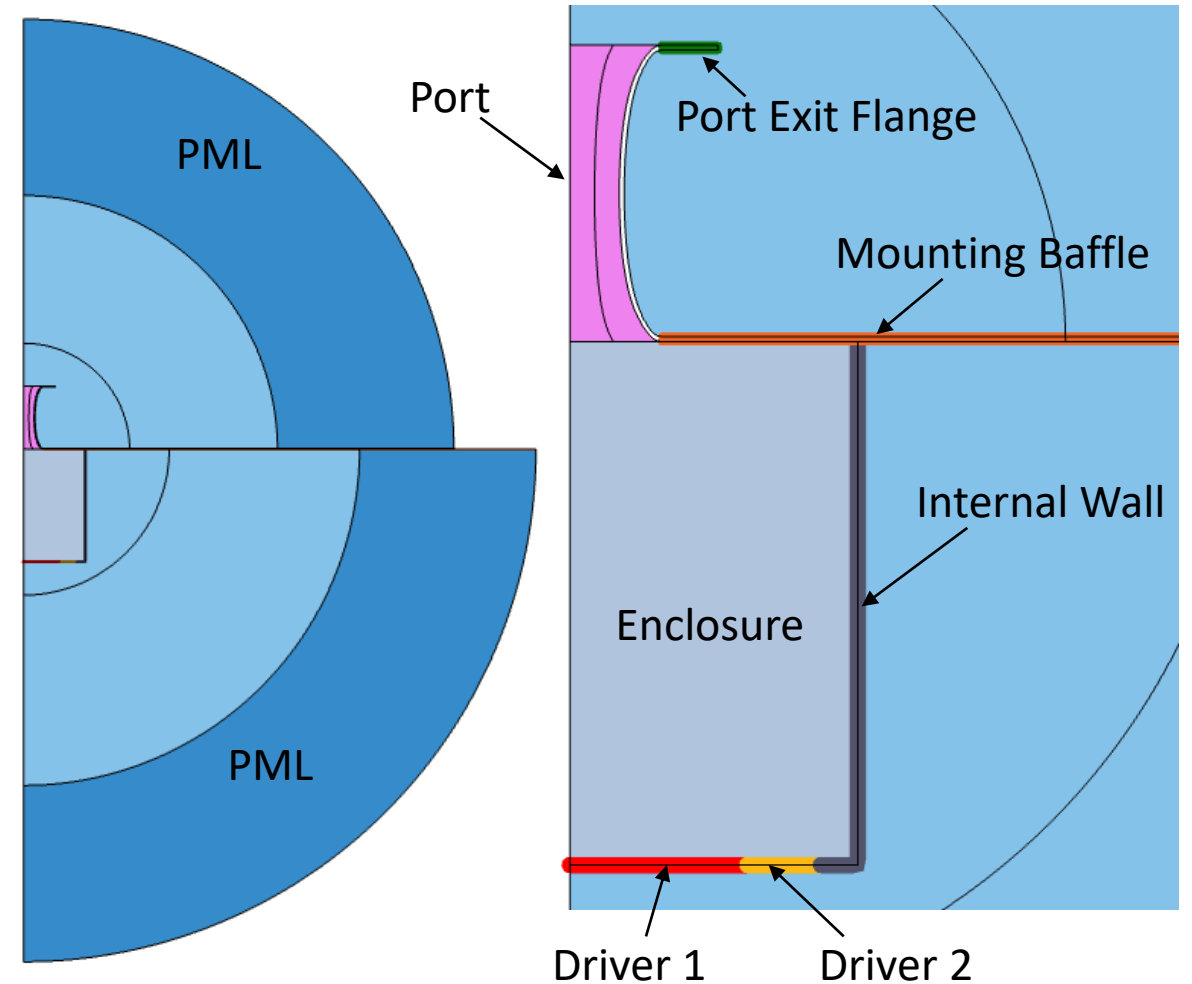

- Near-field hemi-anechoic measurements
- Measure noise induced by ports
- Correlation with hypothesis and simulation?

## Blind Listening Tests

- Near-field recordings
- Double-blind playback through high-end headphones
  1. Rating of sound quality
  2. How much louder can optimal ports play?
- Correlation with hypothesis, simulation, and measurements?

# Simulation Setup

- Axisymmetric
- Acoustic-structure interaction
- Electrical circuit model for loudspeaker driver
- 3 optimization routines
  1. Find box volume for 40 Hz tuning
  2. Find optimal flare rate
  3. Find slightly over- and under-flared profiles with same 40 Hz tuning

# Simulation Results

3:1  
(L = 180 mm)

57 mm

59 mm 

61 mm

Straight with blends

Straight no blends

Over flared

Optimally flared

Under flared

4:1  
(L = 240 mm)

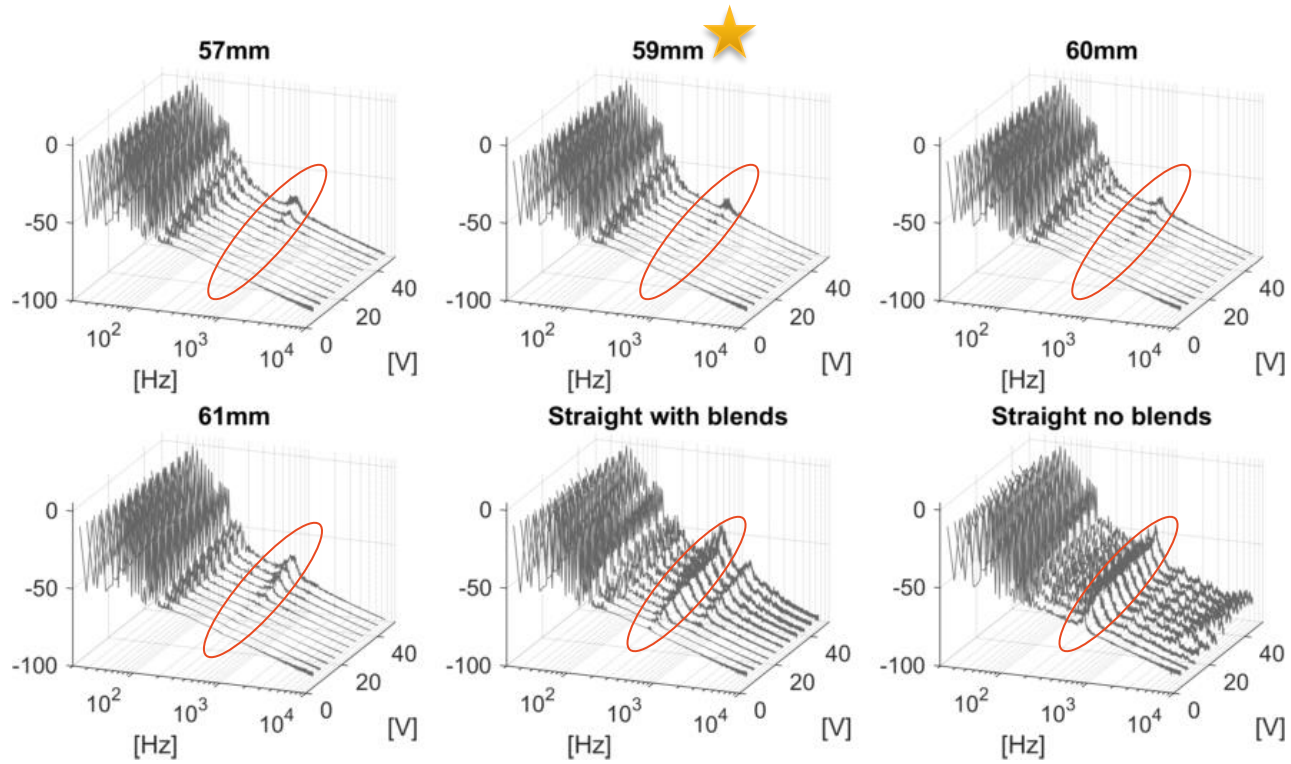

# Measurements

- Hemi-anechoic ( $2\pi$ ) chamber
- 2 x 10-inch woofers
- Near-field measurement with G.R.A.S 46 AM microphone
- Signal: Multi-sine from 20 Hz to 80 Hz for 3:1 ports, 40 Hz sine for 4:1 ports

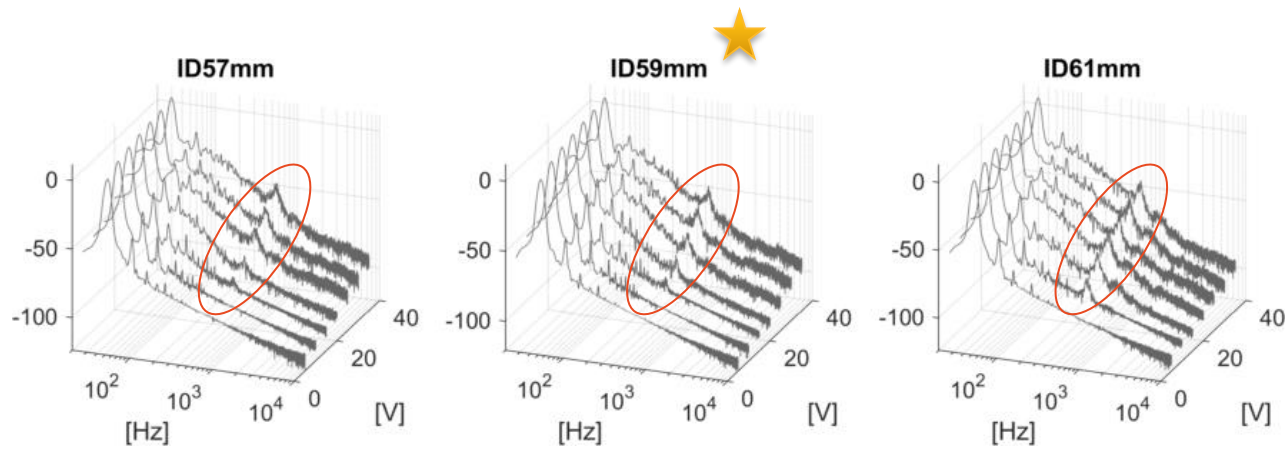

# Measurement Results

## 3:1 Ports

# Measurement Results

## 4:1 Ports

# Double-Blind Listening Tests

## Preference Test

- 3 different sound files with fundamental at 40 Hz
  - Kick drum
  - Whale drum
  - Bass guitar
- Recorded at 4, 20, 40, 60 V
- Playback through headphones, normalized for loudness
- *Preference scale 0-100*

## Method of Adjustment Test

- Whale drum signal
- Reference is 59 mm port at 52 V
- *Adjust drive level until port noise is equally objectionable*

Whale drum examples at 52 V:

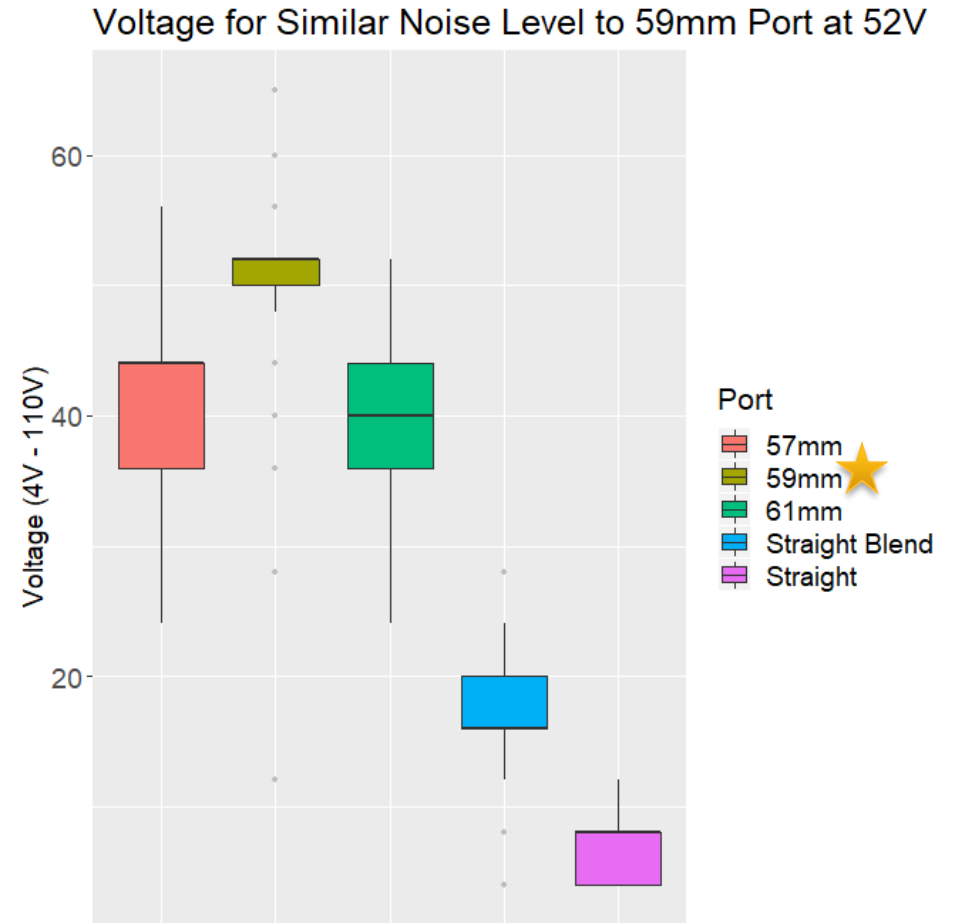

# Listening Test Results

## Preference Test

## Method of Adjustment Test

# Conclusions

- Optimal amount of flare is now predictable!
- Acoustic simulations are fast and amenable for optimization
- Simulations, measurements, and listening tests correlate and validate the hypothesis:

*“The best sounding port has the lowest propensity for flow separation.”*

*Flow separation is minimal when the particle velocity contours at port exit have minimal curvature.”*

- Optimally flared ports can be played *>10 dB louder* than straight ports!
- Optimally flared ports can be played *>1 dB louder* than slightly under- or over-flared ports

# SAMSUNG

## Thank you!
